METHODOLOGY

Universe and peer groups. A global large-cap universe spans the US, Western Europe, Japan and Hong Kong. Annual hierarchical spectral clustering combines return relationships, standardized financial ratios and business characteristics to identify comparable companies.

Signals and selection. Regional six-factor models estimate stock-specific alpha over a rolling one-year window. Alpha and 12-minus-1-month price momentum rank names within peer groups, targeting 70 longs and 20 shorts while retaining holdings whose trends persist.

Portfolio construction. Joint long-short optimization uses Ledoit-Wolf covariance shrinkage to balance expected return, risk and trading costs. Issuer, sector and major factor exposures are constrained; momentum exposure remains flexible and the short book can vary in size.

Rebalancing and continuity. Daily signal reviews and trade thresholds guide execution. Net NAV deducts trading and borrowing costs. The October continuation carries forward positions without a capital reset, using locally constructed regional factors and the last available annual universe and clusters.
